*Aeromonas hydrophila* is a pathogen that causes disease in a wide range of homeothermic and poikilothermic hosts due to its multifactorial virulence. The production of many of these virulence determinants is associated with high cell density, a phenomenon that might be regulated by quorum sensing. The quorum sensing system regulates the expression of several virulence factors in a wide variety of pathogenic bacteria. To investigate the pathogenic role of quorum sensing system in *A. hydrophila*, we constructed an *ahyI* mutant strain of a fish-clinical isolate YJ-1, named YJ-1*Δ*Ahyl. Compared with the wild-type strain, the *ahyI* mutant strain exhibited a significant decrease of total extracellular virulent activity, and decreased in biofilm formation, intraperitoneal LD₅₀ of YJ-1*Δ*Ahyl were more than 10⁹ CFU, about 10⁴ times higher than the parent strain. These results suggest that *A. hydrophila* is able to regulate its extracellular virulent factors and biofilm formation by quorum sensing systems, and indicate that disruption of quorum sensing could be a good alternative strategy to combat infections caused by *A. hydrophila*.

Key words: *Aeromonas hydrophila*, quorum sensing, biofilm, virulence factors.

INTRODUCTION

*Aeromonas hydrophila* is a ubiquitous Gram-negative bacterium of aquatic environments, which has been implicated as a causative agent of motile aeromonad septicemia in a variety of aquatic animals especially freshwater fish species (Hänninen et al., 1997). It causes gastrointestinal and extraintestinal infections in humans, including septicemia, wound infections, gastroenteritis and peritonitis (Daskalov, 2006). A number of virulence factors have been identified in *A. hydrophila*, such as, adhesins (e.g. pili), S-layers, exotoxins such as hemolysins and enterotoxin, and a repertoire of exoenzymes which digest cellular components such as proteases, amylases, and lipases (Cahill, 1990; Pemberton, 1997).

Quorum sensing (QS) (Fuqua et al., 1994) is a mechanism for controlling gene expression in response to an expanding bacterial population. In many Gram-negative bacteria, the diffusible quorum sensing signal molecule is a member of the N-acylhomoserine lactone (AHL) family (Fuqua et al., 1994; March and Bentley, 2004). Several virulence-associated phenotypes in pathogens have been shown to be controlled by their quorum sensing systems (Winzer and Williams, 2001). These phenotypes include biofilm formation (Croxatto et al., 2002), the production of virulence factors such as proteases (Swift et al., 1997, 1999; Croxatto et al., 2002), haemolysin (Kim et al., 2003), a type III secretion system (Henke and Bassler, 2004), extracellular toxin (Manefield et al., 2000) and a siderophore (Lilley and Bassler, 2000). *A. hydrophila* has been found to have homologues of the *Vibrio fischeri* quorum sensing genes *luxI* and *luxR*, designated *ahyI* and *ahyR* (Swift et al., 1997). In this study, we explored the role of the *ahyRI* dependent QS system of *A. hydrophila* by constructing an analysis of the *ahyI* mutant.

We evaluated whether deletion of the *ahyI*

gene affected biofilm formation, motility, extracellular virulence and the pathogenicity in a fish model of infection.

MATERIALS AND METHODS

Bacterial strains, media and growth conditions

The bacteria and plasmids used are listed in Table 1. Escherichia coli DH5α, plasmid-containing E. coli strains, A. hydrophila and its derivative strains were grown in LB medium. E. coli strains were grown at 37°C, while A. hydrophila strains were routinely grown at 28°C. Chromobacterium violaceum CV026 was kindly provided by Dr. McLean (Texas State University) and was grown in LB medium at 30°C. Media were solidified with 1.5% (wt/vol) agar as needed. Antibiotics were added as required at the following final concentrations: ampicillin, 100 μg ml⁻¹; kanamycin, 50 μg ml⁻¹.

DNA manipulation

Genomic DNA of A. hydrophila YJ-1 was prepared as previously described (Sambrook et al., 1989). Plasmid DNA from E. coli was extracted using a plasmid purification kit (Shanghai Shenggong Co. Shanghai) according to the manufacturer’s instructions. Taq DNA polymerase and restriction enzymes were obtained from Takara (Takara Bio. Inc., Dalian, China); and incubation conditions were as recommended by the suppliers.

Construction of A. hydrophila ahyl mutant

To obtain single defined insertion mutant in gene ahyl, we used a method based on the suicide pFS100 (Rubires et al., 1997). Briefly, an internal fragment of the selected gene was amplified by polymerase chain reaction (PCR) using A. hydrophila YJ-1 chromosome, ligated into pGEM-Easy (Promega). Oligonucleotides ahyl-F (5' - CACGGGAAACGTTTATCCG - 3') and ahyl-R (5' - ACCGAATTTATCGCTTCCGG - 3') were used to amplify the internal fragment of ahyl gene from A. hydrophila YJ-1 by PCR. The PCR product was ligated to pGEM-T vector (Promega) and transformed into E. coli DH5α. The internal fragment was recovered by EcoRI restriction digestion, and finally ligated into EcoRI digested suicide plasmid pFS100 plasmid vector. The ligation product was transformed into E. coli CC118 (λpir) and selected for kanamycin resistance. The recombinant plasmid was isolated and transformed into the A. hydrophila YJ-1 strain to obtain the ahyl insertion mutant. The insertion of plasmid on the chromosomes of the mutant was confirmed by PCR with appropriate primers.

Complementation of the A. hydrophila YJ-1 ahyl mutant

To complement the ahyl mutant strain of A. hydrophila, a 1972 bp fragment containing ahylR open-reading frame (ORF), including its promoter, was amplified from A. hydrophila genomic DNA by using two -primers - ahylIR-RI/Satl - 5' - GGCGTCGACGAGCTTGTATCAGCGCCG-3' and ahylIR-RI/EcoRI 5' - GGGAATTCATGAACCGTGCCACAGTGA-3'. The amplified product was ligated into pGEM-Easy vector creating pGEMT-ahylIR. pGEMT-ahylIR was then introduced into the YJ-1∆Ahyl strain by electroporation. Clones exhibiting resistance to ampicillin (100 μg ml⁻¹) were chosen for further study. The presence of luxS on pGEMT-ahyl was confirmed by sequencing. To exclude the possible influence from the vector, the empty vector was electroporated into A. hydrophila YJ-1∆Ahyl as a control strain.

AHL bioassays

Chromobacterium violaceum CV026 was used as a biosensor to detect AHL. The AHL detection was applied by cross-streaking test
strains against C. violaceum CV026 on nutrient agar plate, in which the purple pigment violacein can be restored in response to the presence of AHL molecules. Briefly, strain CV026 was streaked at the center of the nutrient agar plate, the target bacteria were streaked on the same plate against CV026 line, if the target bacteria have AHL-producing ability, diffusible AHL produced by the target bacteria induces strain CV026 to produce a purple pigment (McClellan et al., 1997). C. violaceum CV026 (a mini-Tn5 mutant) was used as an indicator strain for the detection of C4 and C6-HSLs.

Motility assay

LB medium containing 0.3% (wt/vol) agar was used to characterize the motility phenotype of wild type (wt) A. hydrophila YJ-1 and its ahyl mutant strain. The plates were then wrapped with Saran Wrap to prevent dehydration and incubated at 30°C for 12 to 14 h, and the motility was assessed by examining migration of bacteria through the agar from the center towards the periphery of the plate.

Detection of extracellular virulence factors

Some extracellular virulence factors activities were detected by patching bacteria on LB agar plates supplemented with different substrates (Swift et al., 1999). All strains were tested in duplicate, and when results were different, a third experiment was carried out to resolve the discrepancies.

Hemolytic activity was tested on agar base (Oxoid) supplemented with 5% sheep erythrocytes. The culture was streaked onto the plates and incubated at 27°C for 24 to 36 h. The presence of a clear colourless zone surrounding the colonies indicated β-hemolytic activity. Protease production and proteolytic activity was detected on 1.2% agar plates supplemented with 10% (v/v) sterile skimmed milk (105°C for 30 min). The cultures were streaked on the skim milk agar plates and incubated at 27°C for 24 to 36 h. Proteolytic strains caused a clearing zone around the colonies. Lipase activity was assayed on 0.5% tributyrin (Panreac, Barcelona, Spain) agar emulsified with 0.2% Triton X-100 and incubated at 27°C for 24 to 36 h. The presence of a transparent zone around the colonies indicated lipase activity. Extracellular nucleases (DNases) were determined on Dnase agar plates (Difco) with 0.005% methyl green. The culture was streaked onto the plates and incubated at 27°C for 24 to 36 h, a pink halo around the colonies indicated nuclease activity.

SDS-PAGE analysis of extracellular proteins

To prepare extracellular proteins, A. hydrophila YJ-1 and YJ-1ΔluxS were grown for 15 h and inoculated into 8 ml of fresh LB (1% inoculum). After incubation for 24 h, the cells were removed by centrifugation at 12,000 x g for 5 min and 4 ml of the separated culture supernatant was combined with 800 μl of 10% trichloroacetic acid. After 10 min at room temperature, the mixture was centrifuged and residues were solubilized in sample buffer composed of 62.5 mM Tris hydrochloride (pH 6.8), 10% glycerol, 5% 2-mercaptoethanol, and 2% SDS. The protein samples were analyzed by SDS-PAGE using 8% gel and stained with Coomassie Brilliant Blue G-250.

Morphological changes in epithelioinoma papillosum cyprini (EPC) cells induced by A. hydrophila

Cytotoxicity of A. hydrophila strains was assayed with EPC cells.

The EPC cells were grown as a monolayer at 25°C in Eagle's minimum essential medium (MEM; Sigma) supplemented with 10% fetal calf serum in a 5% CO2 atmosphere incubator, and harvested with trypsin ethylenediaminetetraacetic acid. A 900 μl aliquot of the cell suspension was inoculated to each well in a 24 well culture plate. After incubation for 24 h, EPC monolayers were infected with A. hydrophila cells (wt and QS mutant) suspended in phosphate-buffered saline (PBS) at a multiplicity of infection (MOI) (number of bacteria per cultured cell) of 1 and incubated for 30 min, after infection, the EPC cells were washed three times with PBS. The cell morphology were examined using an Axiover 25CFL phase-contrast inverted microscope (Carl-Zeiss) at 200 magnifications.

Animal experiments

50±3 g (mean ±SD) Carassius auratus gibelio were obtained from a aquaculture farm in Nanjing, Jiangsu Province, P. R. China. The C. auratus gibelio were kept in 100 L tanks supplied with aerated fresh water and fed with commercial pelleted diet twice a day. The water temperature was kept at (25±1)°C. Before manipulation, the fish were anesthetized with 1:15,000 tricaine methane sulfonate MS-222 (Sigma) in water. For 50% lethal dose (LD50) determinations, six groups of 10 fish were intraperitoneally (i.p.) injected with 0.1 ml of washed culture of A. hydrophila YJ-1 and of A. hydrophila ahyl mutant, emulsified in sterile phosphate-buffered saline containing 10^7 to 10^8 CFU. The fish were observed for 7 days, and any dead specimen was removed for routine bacteriological examination. The experiment was carried out three times in duplicate, and the LD50 was calculated by the statistical approach of Reed and Muench (1938).

Biofilm assay

A quantitative biofilm formation experiment was performed in a microtiter plate as described previously (O'Toole and Kolter, 1998), with minor modification. Briefly, bacteria were grown on LB agar, and several colonies were gently re-suspended in LB (with or without the appropriate antibiotic); 100 μl aliquots were placed in a microtiter plate (polystyrene) and incubated 48 h at 28°C without shaking. After the bacterial cultures were poured out, the plate was washed extensively with water, fixed with 2.5% glutaraldehyde, washed once with water, and stained with a 0.4% crystal violet solution. After solubilization of the crystal violet with ethanol-acetone (80:20, vol/vol) the absorbance at 570 nm was determined using a microplate reader (Bio-Rad, Hercules, Calif.).

Statistical analysis

For animal studies, statistical analyses were performed using Fisher's exact test. For all other studies, Student's t test was used.

RESULTS

Characterization of ahyl mutant strain of A. hydrophila YJ-1

A mutant strain YJ-1ΔAhyl was constructed with a deletion of 147 bp of ahyl (GenBank accession no.X89469). The successful mutant of the ahyl gene was confirmed by PCR and DNA sequencing (data not shown). The CV026 bioassay revealed that the YJ-
Role of quorum sensing in biofilm formation of *A. hydrophila*

Biofilm formation of *A. hydrophila* wild-type and *ahyI* mutant strain, YJ-1ΔAhyl was monitored in microtiter plates. As shown in Figure 3, biofilm formation of YJ-1ΔAhyl was significantly decreased, compared with that of wild-type strain YJ-1, while the complemented strain of YJ-1ΔAhyl, YJ-1ΔAhylC can form biofilm. Thus, quorum sensing has a distinct influence on biofilm formation in *A. hydrophila*.

Fish infection

To ascertain the role of quorum sensing system in the pathogenesis of *A. hydrophila*, the LD50 was determined for *A. hydrophila* YJ-1 and YJ-1ΔAhyl by intraperitoneal challenge of *C. auratus gibelio*. As showed in Table 2, the LD50 values were more than 1.0 x 10^7 CFU bacteria for YJ-1ΔAhyl and 6 x 10^5 CFU bacteria for wild-type respectively. Fish injected with the parental strain died more rapidly than those injected with YJ-1ΔAhyl. All recorded deaths occurred within 4 days when the fish were injected with the wild type; however, deaths were recorded up to 6 days following injection when the fish were injected with YJ-1ΔAhyl. The *ahyI* mutation led to a significant decrease in strain virulence, indicating that quorum sensing system has a role in the pathogenic mechanism of *A. hydrophila*.

Examination of mortality showed typical clinical signs of hemorrhagic septicemia, mainly external lesions (abdominal distension at the injection site) and internal hemorrhages. To confirm stability of the insertional inactivated *ahyI* mutant gene, bacteria were isolated from dead fish inoculated with YJ-1ΔAhyl, all conferring a Kan phenotype.

DISCUSSION

In animal and plant pathogens, such as *Agrobacterium tumefaciens*, *Erwinia chrysanthemi*, *Pseudomonas aeruginosa*, and *Vibrio anguillarum*, AHL systems control the expression of a number of exported products that are proven or putative virulence factors. For example, quorum sensing through AHLs has been shown to be involved in biofilm formation (Kjelleberg and Molinm, 2002), competitive or cooperative bacterial interactions (Keller and Surette 2006) and virulence factors secretion. As described earlier, *A. hydrophila* produces a wide range of virulence factors. These virulence factors are expressed differently, depending on environmental and metabolic aspects of its current habitat. The regulation of many of these virulence factors is based on cell density-dependent cell-to-cell signaling, termed quorum sensing (Lynch et al., 2002; Bi et al., 2007; Khajanchi et al., 2007; Keller and Surette, 2006).

*NA, not applicable: no death due to *A. hydrophila* infection during the experiment.
To explore the role of quorum sensing system in regulating the extracellular virulent factors secretion and biofilm formation, we constructed an ahyl mutant strain of a fish-clinical isolate YJ-1, named YJ-1Aahyl. Inactivation of the ahyl gene of A. hydrophila did not result in noticeable changes in growth patterns compared with those of the wild-type strain. This finding indicates that ahyl has no significant effect on basic cellular metabolic processes required for growth of A. hydrophila in vitro. This is in contrast to some other bacteria in which luxS had an effect on growth. Lyon et al. (2001) reported that disruptions of Streptococcus pyogenes, s luxS shown a media-dependent growth defect, and the effect of quorum sensing on Vibrio harveyi growth rate can be either positive or negative (Nackerdien et al., 2008).

Decreased virulence has been seen in ΔluxS mutants of several pathogenic bacteria (Winzer and Williams, 2001). A Vibrio cholerae luxO mutant is severely defective in colonization of the small intestine in an infant mouse model, inactivation of the rhlA gene in P. aeruginosa prevents rhamnolipid production, disabling the protection against polymorphonuclear leukocytes (Van et al., 2009), and quorum sensing is necessary for the virulence of P. aeruginosa during urinary tract infection (Kumar et al., 2009), and Vibrio alginolyticus luxO-luxRVal regulatory system control the expression of alkaline serine protease (Rui et al., 2009). In contrast, the S. epidermidis luxS mutant shows increased virulence in a model of catheter-associated infection. Most likely, the increased virulence may be partly attributed to the increased synthesis of PIA and more-intense biofilm formation. In this study, virulence factors were detected by patching bacteria on LB agar plates supplemented with different substrates, and the results shown that the virulence factors were decreased in the ahyl mutant strain, and on the PAGE, many proteins bands were lost or decreased, this phenomena suggest that QS control the extracellular proteins production, these band not only include the virulence factors, this results is consistent with the report on the protease.

The biofilm formation has been documented as survival strategy of pathogens, regulation of biofilm formation by quorum sensing systems has been shown in a number of bacteria. In vitro biofilm formation in A. hydrophila has been demonstrated using crystal violet staining assays as well as SEM. We could detect the difference between the parent strain and the QS mutant. Our data showed that the ahyl mutant strain was unable to develop a complete biofilm. This effect on biofilm formation by luxS in vitro was also observed in Streptococcus (Cvitkovitch et al., 2003), Streptococcus (Kong et al., 2006) and V. cholerae (Waters et al., 2008), while the luxS mutant of Edwardsiella tarda (Xiao et al., 2009) and Streptococcus mutans (Huang et al., 2009) were considerably increased biofilm formation. Thus, the quorum sensing signaling molecules have contrasting effects on biofilm formation in different strains.

In conclusion, we show quorum sensing system in A. hydrophila is functional for the secretion of extracellular virulence factors, the formation of mature biofilm and its pathogenicity, and these findings indicate that disrupt quorum sensing systems of pathogenic bacteria is a promising alternative for antibiotics in fighting bacterial infections.

ACKNOWLEDGEMENTS

This work was supported by State Administration for Entry and Exit Inspection and Quarantine of P. R. China. The authors are much indebted to Dr. RJC McLean, Department of Biology, Texas State University, for generous provision of the AHL bioassay strain and for his helpful comments on the manuscript.
