Received 15 September, 2013; Accepted 5 February, 2014

This study was conducted to investigate the antimicrobial activities of the methanolic extract of *Rothmannia longiflora* and *Canna indica* leaves against 10 pathogenic bacterial and fungal strains. The methanolic extract from the two plants were screened for their minimum inhibitory concentration (MIC) against the microbial growth of *Staphylococcus aureus*, *Escherichia coli*, *Bacillus subtilis*, *Pseudomonas aeruginosa*, *Salmonella typhi*, *Klebsiella pneumonia*, *Candida albicans*, *Aspergillus niger*, *Phytophthora stolomer* and *Penicillium notatum*. The results show that inhibition of microbial growth decreased with decreasing concentrations of the plant extracts. While concentrations of 200 and 100 mg/ml completely inhibited microbial growth, lower concentrations (50 and 25 mg/ml) showed partial inhibition, extracts at lower concentrations than these had no effects on microbial growth of microorganisms tested. Comparatively, *R. longiflora* gave better results than *C. indica*. This study confirmed the effectiveness of methanolic extracts of the two plants as inhibitory effect to microbial growth of several pathogenic microorganisms and testified to the basis of the ethnomedicinal uses of these two plants against several microbial infections.

**Key words:** Antimicrobial potential, *Rothmannia longiflora*, *Canna indica*, bacteria, fungi, Nigeria, methanolic extract.

**INTRODUCTION**

Plant-derived substances have recently become of great interest owing to their versatile applications. Medicinal plants are the richest bio-resource of drugs of traditional systems of medicine, modern medicines, nutraceuticals, food supplements, folk medicines, pharmaceutical intermediates and chemical entities for synthetic drugs. The increase of microbial infections have increased dramatically in the past 20 years because of the increase in the number of people whose immune systems are compromised by AIDS, aging, organ transplant and cancer therapy.

Accordingly, increase in the rates of morbidity and mortality because of microbial infections have been regarded as a major problem (Tatli and Akdemir, 2005). Worse still, there are global problems of multiple antibiotics resistance as well as emergence of new and resurrection of previously eradicated diseases. Most of the current antimicrobial drugs simply reduce the level of growth of bacteria or fungi, and some of them are very toxic to the kidney, the hematopoietic and central nervous system.
system (Tatli and Akdemir, 2005). Furthermore, antimicrobial resistance among enteric pathogens is becoming a matter of serious concern (El-Mahmoud et al., 2008) and poses a great threat to global human health. Further, new microbial strains are being continuously discovered, which are refractory to the current arsenal of drugs (Erturk et al., 2006). This is because antimicrobial resistance leads to therapeutic failures of empirical therapy (Parekh and Chanda, 2007).

As a result, it has become necessary to fight against emerging and re-emerging infectious diseases with a view to discover and invent new agents of greater therapeutic profile to mitigate frequent outbreaks of diseases which has posed a new threat to global health security (Mohanta et al., 2007). The continuous evolution of bacterial resistance to currently available antibiotics has necessitated the search for novel and effective antimicrobial compounds (Fagbemi et al., 2009), to which these micro-organisms are yet to develop resistance (El-Mahmoud et al., 2008).

With the rising problems of side effects and limited efficacy of antibiotic drugs (Gupta et al., 1998), there is an urgent need for the development of alternative antimicrobial substances and researchers are nowadays turning to natural products from plants (Nitta et al., 2002), as their main source of bioactive compounds with antimicrobial properties, to complement the existing synthetic antimicrobial drugs that are gradually becoming less potent against pathogenic microorganisms (Lawal et al., 2012).

The rate of interest in plant derived drugs has shoot up due to the fact that herbal medicine is safer and less costly than the synthetic drugs which possess serious side effects. It is therefore necessary to screen plants for promising biological activity (Lawal et al., 2010).

**Rothmannia longiflora** Salisb. is a shrub belonging to the plant family of Rubiaceae, having trumpet-like flower with fruits that are longitudinal in shape. It has been reported to have antimalarial effects and also used in the treatment of measles and to give tribal marks (Ikpi et al., 2009). It is used as chewing stick in the treatment of filariasis, dysentery, and fever and also as an analgesic and emetic. Furthermore, the plants is considered to have febrifugal and analgesic properties, and a decoction of the leaves, twigs, bark and roots is applied internally or externally in lotions, washes and baths. In Nigeria the roots are used to treat bowel complaints (Jansen, 2005).

The plant, *Canna indica* L. is a native of the Caribbean and Tropical America; and belongs to the family Cannaceae. The introduction of this plant to Africa, especially Nigeria is unknown, but it is widely distributed throughout Nigeria, where it is known locally as “ebesalebo” in Edo, “nkwa eboti” amongst the Efik, “bakalekale” in Hausa, “aberekamwo” in Igbo land and “iroro” amongst the Yorubas. It has been reported to be used ethnomedically for the treatment of malaria in South-western Nigeria, as well as a cure for diarrhoea and dysentery and in the treatment of fever, bruises and cut (Odagbemi et al., 2007). Josephine et al., 2013 reported that methanolic extracts of *C. indica* possessed anti-diarrhoeal properties.

This study was therefore conducted to investigate the antimicrobial activities of the methanolic extract of *R. longiflora* and *C. indica* leaves on some bacterial and fungal strains.

**MATERIALS AND METHODS**

**Plant materials**

Fresh leaves of *R. longiflora* and *C. indica* were collected from Forestry Research Institute of Nigeria. The plants confirmation and identification was done at Forest Herbarium, Ibadan (FHI) in Forestry Research Institute of Nigeria (FRIN). The leaves were air dried for five days and pulverised using hammer mill and kept for analysis.

**Test micro-organisms**

A total of 10 test microorganisms used in this study, which include bacterial and fungal strains. The bacteria species used are *Staphylococcus aureus*, *Escherichia coli*, *Bacillus subtilis*, *Pseudomonas aeruginosa*, *Salmonella typhi* and *Klebsiella pneumonae*; while the fungi species include *Candida albicans*, *Aspergillus niger*, *Phajapus stolometer* and *Penicillium notatum*. The micro-organisms were collected from Departments of Pharmaceutical Microbiology and Veterinary Microbiology of the University of Ibadan and the International Institute of Tropical Agriculture (I. I. T. A), Ibadan.

**Preparation of the extracts**

100 g of the powered plant leaf samples were macerated with 100 ml of 90% methanol for 72 h and pooled to obtain the crude methanol extract. The extract was filtered through filter paper to remove all insoluble matter, including cellular materials.

**Antimicrobial assays**

4 ml of the sample was measured into the first test tube and five other test tubes contained 2 ml of methanol. From the first tube that contains 4 ml of the original sample, 2 ml was taken into the second tube to make up to 4 ml. This was done until the 6th test which was the last test tube for the extract. The 7th and 8th tubes contain positive and negative controls respectively.

**Pour plate method (Bacteria)**

An overnight culture of each organism was prepared before taking scooping of the organism from the stroke and inoculated each into the sterile nutrient broth of 5 ml for 18 - 24 h at 37°C. From overnight culture 0.1 ml of each organism was taken into 9.9 ml of sterile distilled water to get (1:10) 10⁻² of the dilution of the organism.

From the diluted organism, 0.2 ml was taken into the prepared sterile nutrient agar which was incubated at 45°C. These were then aseptically poured into sterile petri dishes and allowed to solidify for about 45 min, using a sterile cork -borer. The wells were made accordingly into the graded concentrations of the extract including...

**RESULTS AND DISCUSSION**

The study was conducted to investigate the antimicrobial potentials of the methanolic extracts of *R. longiflora* and *C. indica* on 10 selected pathogenic micro-organisms. The antimicrobial potentials of these 2 plants were determined based on the zones of inhibition of microbial growth of the test micro-organisms. The mean zones of inhibition of growth of the isolates are a function of relative antibacterial and anti-fungal activities of the extracts. The zone of inhibition is simply the area on the agar plate that remains free from microbial growth. The size of the zone of inhibition is usually related to the level of antimicrobial activity present in the sample or product - a larger zone of inhibition usually means that the antimicrobial is more potent (Lawal et al., 2012). Some of the plates exhibited clearly distinct zone of inhibition, while some of them did not. Tables 1 and 2 present the calculated mean zones of inhibition (mm) of methanolic leaf extracts of *R. longiflora* and *C. indica* on the bacterial and fungal strains used for this study respectively.

The results show that at the higher concentrations of 200 and 100 mg/ml, methanolic extracts of *R. longiflora* showed inhibition of all the microorganisms (Table 1). The results were similar at the same concentrations in *C. indica*, except for *P. aeruginosa* at 100 mg/ml (Table 2). Inhibition of the methanolic extracts of these plants reduced with decreasing concentrations, with no inhibition recorded at concentrations of 12.5 mg/ml and lower (Tables 1 and 2). Comparatively, *R. longiflora* showed higher inhibition to microbial growth than *C. indica*.

Resistant bacteria have become commonplace in healthcare institutions and increased mortality rate due to resistant *P. aeruginosa*, *S. aureus*, *K. pneumoniae*, *E. coli*, *Enterobacter* spp., and coagulase-negative staphylococci and enterococci has been reported (Karlosky et al., 2003; NNIS, 2004; Kang et al., 2005). With this increased incidence of antimicrobial resistance and appearance of new infectious for their antimicrobial activity and resistance modifying ability (Gibbon, 2004; Coutinho et al., 2009). While the natural products are known to play significant roles in the development of novel drugs and served as leads for the treatment and

Gmc, Gentamycin; na, not active.

prevention of diseases (Belini et al., 2008), plant-derived antimicrobials provide the much needed therapeutics (Olajuyigbe and Afolayan, 2013).

The leaves of C. indica showed antimicrobial activity (Abdullah et al., 2012), analgesic activity, and the rhizomes showed a good anthelmintic activity against Pheritima posthuma (Nirmal et al., 2007). The leaves haves chemical constituents like lignin, furfural and hemicelluloses, while rhizomes has 5,8- Henicosidine, Tetracosane and Tricosane (Deming and Tinoi, 2006). The water extract of rhizomes of C. indica has been reported to have HIV-1reverse transcriptase inhibitory activity (Woradulayapinij et al., 2005) while its essential oil shows antibacterial activity (Indrayan et al., 2011). Methanolic extract of Aerial Parts of C. indica shows antioxidant activity (Joshi et al., 2009). Furthermore, anthocyanins and methylated anthocyanidin glycosides were also isolated from C. indica flowers (Srivasta and Vankar, 2010; Srivasta and Vankar, 2010).

Previous studies have shown that R. longiflora is the only higher plant that possessed 4-oxonicotinamide-1-(1'-β-D-ribofuranoside), which is only found in human urine. It is an interesting compound, particularly in influencing enzymatic processes. Furthermore, Ebigwai et al., 2012 reported the larvicidal effects and use of R. longiflora extracts against Simulium yahense larvae. S. yahense is responsible for causing onchocerciasis.

**Conclusion**

This study has confirmed the effectiveness of methanolic extracts of the two plants as inhibitory to microbial growth of several pathogenic microorganisms. Furthermore, the results explain the basis of the ethnomedicinal uses of these two plants against several microbial infections. However, further studies might be required to isolate the active ingredients in the plants.
